

Parents' Support for School-Entry Requirements for Human Papillomavirus Vaccination: A National Study

William A. Calo¹, Melissa B. Gilkey^{2,3}, Parth D. Shah⁴, Jennifer L. Moss^{4,5}, and Noel T. Brewer^{4,6}

Abstract

Background: The number of states proposing school-entry requirements for human papillomavirus (HPV) vaccination has increased over the last decade. However, data are currently limited regarding parents' support of such laws. We sought to obtain the first national estimates of parents' support of HPV vaccination school-entry requirements.

Methods: A national sample of 1,501 parents of 11- to 17-year-old children completed a web-based survey between November 2014 and January 2015. Analyses used multivariable logistic regression to assess correlates of support for school-entry requirements for HPV vaccination.

Results: Overall, 21% of parents agreed that laws requiring HPV vaccination for school attendance "are a good idea," and 54% disagreed. If school-entry requirements included opt-out provisions, agreement increased to 57%, and only 21% disagreed. Parents more often agreed with requirements without opt-out

provisions if they were Hispanic [OR = 1.53; 95% confidence interval (CI), 1.05–2.22], believed HPV vaccine was as or more important than other adolescent vaccines (OR = 2.76; 95% CI, 1.98–3.83), or believed HPV vaccine was effective for preventing cervical cancer (OR = 2.55; 95% CI, 1.93–3.37). Parents less often agreed if they resided in Midwest states or believed that HPV vaccine was being pushed to make money for drug companies (both $P < 0.05$).

Conclusion: Opt-out provisions almost tripled parents' support for HPV vaccine school-entry requirements. Our findings suggest that race/ethnicity, attitudes about HPV vaccine, and region of residence may influence support for requirements without opt-out provisions.

Impact: Opt-out provisions greatly increase parent support of school-entry requirements for HPV vaccination but may make them ineffective. *Cancer Epidemiol Biomarkers Prev*, 25(9); 1–9. ©2016 AACR.

Introduction

Human papillomavirus (HPV)-attributable diseases are a serious public health threat in the United States (1). Nearly 80 million Americans are infected with at least one type of HPV (2), and HPV types 16 and 18 are responsible for more than 22,000 new cases of cancer each year (3). Most HPV-associated cancers could be prevented through widespread HPV vaccination (1). For this reason, national guidelines recommend routine and timely HPV vaccination of boys and girls at age 11 or 12 (4). However, HPV vaccine coverage is low, lagging far behind other adolescent

vaccines. Among 13- to 17-year-olds, only 40% of girls and 22% of boys had completed the HPV vaccine series by 2014 (5). These coverage levels fall considerably short of the Healthy People 2020 goal of having 80% of 13- to 15-year-olds fully vaccinated (6).

In the United States, policy interventions, such as school-entry requirements, have contributed to high uptake of adolescent vaccination and, in turn, low prevalence of many vaccine-preventable diseases (7–9). The Task Force on Community Preventive Services recommends school-entry requirements as an evidence-based strategy to increase vaccine coverage (10). Requiring vaccination as a condition to school attendance is within state's legislative power to protect the public's health. As of 2016, all 50 states and Washington, D.C. have vaccine requirements for school entry. All of these laws allow for medical exemptions (11), which typically require a physician's certificate stating that a vaccination would be harmful. Most states also allow nonmedical exemptions; 47 states permit religious exemptions and 18 states allow philosophical exemptions on the basis of personal, moral, or other beliefs against vaccination (11). States differ in the process parents must go through to get a nonmedical exemption (12–14). In states where there is no rigorous process for claiming the exemption, more people opt out of vaccination (15).

The unprecedented opportunity to prevent HPV-associated cancers through vaccination led many states to propose laws requiring HPV vaccine for school attendance, similar to those for tetanus, diphtheria, and pertussis (Tdap). Since Michigan

introduced the first legislation requiring HPV vaccination for school entry in September 2006, 24 other states and Washington, D.C. have proposed similar laws (16). However, only Virginia and Washington, D.C. have enacted such legislation into law, with Rhode Island more recently adopting the policy by means of administrative ruling. Ethical, political, and legal concerns from opponents have been the focus of the policy debate (17–19), shifting discussions away from the demonstrated effectiveness of HPV vaccination to prevent many cancers (20, 21).

Policy makers consider their constituents' opinions as they decide how to act on health policies (22), including HPV vaccination school-entry requirements (17). However, data are currently limited regarding parents' support for these laws. Previous studies were limited to samples in Georgia (23), North Carolina (24), and Los Angeles, California (25) and happened prior to ACIP recommendations that boys routinely receive HPV vaccination. To fill this large gap in the literature, we conducted a national survey among parents of 11- to 17-year-old boys and girls to better understand their support for these laws. The aims of our study were to: (i) assess parents' support for HPV vaccine school-entry requirements, without and with opt-out provisions, and (ii) identify correlates of parental support for such laws. We hypothesized higher support for school-entry requirements when including opt-out provisions and among parents with positive attitudes about HPV vaccine.

Materials and Methods

Participants and procedures

Participants were members of an existing, national panel of non-institutionalized U.S. adults maintained by a survey research company (26). The company constructed the panel using probability-based sampling of list-assisted, random-digit dialed (RDD) phone numbers supplemented by address-based sampling (ABS). The ABS strategy was incorporated in response to the growing number of cell phone-only households that are outside the traditional RDD landline telephone frame. Thus, our overall sampling design captured households with landline phones, cell phone-only households, and households without telephones. Eligible panel members were parents of at least one 11- to 17-year-old child living primarily in their households. The survey instructed respondents with more than one age-eligible child to respond with regard to the child with the most recent birthday.

The survey company emailed invitations to a random sample of 2,845 panel members, and 1,760 responded by visiting the survey website, confirming eligibility criteria, and providing informed consent. A total of 1,504 parents were eligible and completed the survey between November 2014 and January 2015. After accounting for ineligible respondents ($n = 335$) and excluding respondents who failed to complete at least two-thirds of the survey ($n = 14$), the survey response rate was 61%, calculated using American Association for Public Opinion Research Response Rate 5 (27). For the current study, we also excluded respondents who did not provide data on the main outcome variable ($n = 3$). The final analytic sample had 1,501 parents. Forty-three respondents (3% of the sample) came from Virginia and Washington, D.C., which had HPV vaccine school-entry requirements in place at the time of the survey. Since we sought to obtain the first national estimate of support for such requirements, we included these parents in our sample.

Prior to fielding the survey, we cognitively tested our instrument with 18 parents of adolescents to maximize respondent comprehension. We then pretested the survey online with 26 panel members to ensure proper functioning. The survey instrument is available online at www.unc.edu/~ntbrewer/hpv.htm. The University of North Carolina Institutional Review Board approved the study protocol.

Measures

Following the approach of previous studies (24, 25), our survey introduced respondents to HPV vaccine school-entry requirements with the prompt, "Some states are trying to pass laws that would require all 11 and 12 year-olds to get HPV vaccine before they are allowed to start 6th grade." Parents then said whether they agreed with the statement, "I think these laws are a good idea" using a 5-point response scale. Parents who did not agree with the previous statement received an additional item: "It is okay to have these laws only if parents can opt out if they want to." For each statement, we categorized parents as agreeing (somewhat or strongly agree) or disagreeing/neither (somewhat or strongly disagree, or neither disagree or agree).

The survey assessed key candidate correlates previously identified in the literature as potential predictors of parental support of HPV vaccine school-entry requirements (24, 25). The survey company provided data on parents' sex, race/ethnicity, educational attainment, annual household income, and location of residence in terms of U.S. state and region. We created a variable to assess whether respondents had their residence in a state that requires HPV vaccination for school attendance. We dichotomized this variable as yes (respondents from Virginia and Washington, D.C.) and no (respondents from other states). The survey also assessed the sex and age of the index child, and whether parents had received a provider recommendation for HPV vaccination for that child. The survey assessed HPV vaccination status with one item: "How many shots of the HPV vaccine has [child's name] had?" We defined HPV vaccine initiation as responses of ≥ 1 shots.

Rules or regulations (e.g., requiring vaccination for school attendance) that people perceive as threatening personal freedoms can elicit a motivational state, reactance, which is characterized by anger and counter arguing and may elicit oppositional behavior (e.g., refusing vaccination; ref. 28). The survey assessed psychologic reactance with three items: "I become frustrated when I am unable to make free and independent decisions," "Regulations trigger a sense of resistance in me," and "When someone forces me to do something, I feel like doing the opposite." These items had a 5-point response scale that ranged from "strongly disagree" to "strongly agree". We created an index of reactance by calculating the mean response value and creating two categories: low (< 4) and high (4–5).

The survey assessed parents' agreement with statements shown to be associated with HPV vaccination uptake in the United States (29) and support for school-entry requirements for HPV vaccination (24, 25). The survey assessed perceptions regarding harms of HPV vaccines (e.g., "The HPV vaccine might cause lasting health problems"), barriers to vaccination (e.g., "It would be hard to find a provider or clinic where I can afford HPV vaccine for my child"), vaccine effectiveness (e.g., "The HPV vaccine is effective in preventing cervical cancer"), and uncertainty about the vaccine (e.g., "I don't have enough information about the HPV vaccine to decide whether to give it to my child"). We adapted these items

from the Carolina HPV Immunization Attitudes and Beliefs Scale (29). The 5-point response scale ranged from "strongly disagree" to "strongly agree."

The survey also assessed importance of HPV vaccination with the statement: "I felt that the HPV vaccine for [child's name] is. . .," accompanied by a 5-point response scale that ranged from "not important" to "extremely important." The survey repeated the same statement for meningococcal and Tdap vaccines. We calculated relative vaccine importance, giving a score of 1 if parents rated HPV vaccine as important as, or more important than, the average score for Tdap and meningococcal vaccines and 0 otherwise.

Statistical analysis

We calculated the percentage of support for HPV vaccine school-entry requirements, without and with opt-out provisions. We used bivariate logistic regressions to identify bivariate associations of candidate correlates with support for HPV vaccine requirements. We then entered covariates showing associations ($P < 0.05$) in bivariate analyses into a multivariable logistic regression model. We used separate logistic regression models to assess the associations between potential correlates and HPV vaccine requirements without and with opt-out provisions. Statistical tests were two-tailed with a critical alpha of 0.05. We conducted analyses using Stata 12.0.

Results

Respondents included residents of all 50 states and Washington D.C., and 33% were from the South (Table 1). About one-fifth (22%) had a household income of less than \$35,000 per year. Parents were evenly split between having reported on a son (51%) or a daughter (49%), and the mean age of children was 14 years. Forty-six percent of children had received at least 1 dose of HPV vaccine. Fifty-six percent of parents were female, and the majority were non-Hispanic white (70%) or Hispanic (14%). More than one-third (38%) of parents had a high school degree or less education. Almost three-fourths (73%) of the sample scored low in the 3-item index of psychologic reactance. About half (52%) of parents had received a provider recommendation for HPV vaccination.

Regarding HPV vaccine attitudes, about half (51%) of parents said that HPV vaccine was as or more important than the Tdap and meningococcal vaccines (Table 1). Nearly one-fourth (23%) of the sample thought that HPV vaccine might cause lasting health problems and about one-third (32%) thought that HPV vaccine was being pushed to make money for drug companies. Thirty-two percent of parents said that they did not have enough information about HPV vaccine to decide whether to vaccinate their children and only 40% agreed that the vaccine was effective in preventing cervical cancer. Few parents (6%) said that it would be hard to find a provider or clinic where they can afford HPV vaccine for their children.

Support for HPV vaccine requirements without opt-out provisions

Twenty-one percent of parents agreed that laws requiring HPV vaccination for school attendance "are a good idea" (Fig. 1). Hispanic parents had higher odds [OR = 1.53; 95% confidence interval (CI), 1.05–2.22] of agreeing with HPV vaccine school-entry requirements than non-Hispanic whites in multivariable

analysis (Table 2). Likewise, parents more often agreed with these requirements if they believed that HPV vaccine was as or more important than other adolescent vaccines (OR = 2.76, 95% CI, 1.98–3.83), that HPV vaccine was effective for preventing cervical cancer (OR = 2.55, 95% CI, 1.93–3.37), or that it would be hard to find a provider or clinic where they can afford the vaccine for their children (OR = 2.50; 95% CI, 1.45–4.33). On the other hand, parents less often agreed with school-entry requirements if they believed that HPV vaccines were being pushed to make money for drug companies (OR = 0.47; 95% CI, 0.32–0.69) or resided in Midwest states compared with Northeast states (OR = 0.64; 95% CI, 0.42–0.98). In bivariate, but not multivariate analyses, agreement with school-entry requirements was associated ($P < 0.05$) with living in a state requiring HPV vaccination for school attendance, having initiated HPV vaccination, having received a provider recommendation for HPV vaccination, lower psychologic reactance, and believing that HPV vaccine might cause lasting health problems and that respondents do not have enough information to decide whether to give the vaccine to their children.

Support for HPV vaccine requirements that include opt-out provisions

Support for HPV vaccine school-entry requirements increased to 57% when including parents who agreed "these laws are okay only if parents can opt out" (Fig. 1). Support for HPV vaccine requirements also increased when examined for each variable independently associated with agreeing that school-entry requirements "are a good idea" (Fig. 2). In multivariable analysis, when including agreement with opt-out provisions, parents who believed HPV vaccine was effective in preventing cervical cancer (OR = 2.18; 95% CI, 1.73–2.74) and believed HPV vaccine was as or more important than Tdap and meningococcal vaccines (OR = 1.29; 95% CI, 1.02–1.66) still had higher odds of agreeing with school-entry requirements (data not shown). When opt-out provisions were included, no other variable associated with agreeing school-entry requirements "are a good idea" remained associated in multivariable analysis.

Discussion

The current study, to our knowledge, is the first to employ a national sample to assess parental attitudes about HPV vaccine school-entry requirements. We found that 21% of parents agreed that school-entry requirements "are a good idea." Previous studies reported higher levels of support than we observed; 46% of parents in five southeastern North Carolina counties (24) and 59% in Los Angeles (25) agreed with HPV vaccine school-entry requirements. However, such levels of support could be particular to those study participants and may not be generalizable to the general population because data were collected from individuals who lived in counties with elevated cervical cancer rates (25) or participated in a study about sexually transmitted infections (24). In addition, previous estimates of support could be higher because the response scale did not have a midpoint response option, thus requiring participants to take either side of agree or disagree scale. In the current study, we found that 25% of the sample neither agreed nor disagreed with HPV vaccine school-entry requirements. Although some scholars debate that providing this response option makes it easier to respondents to avoid the mental process necessary to select their true response (30),

others also argue that not everyone has strong thoughts one way or the other, even for very polarized policy issues (31). Public education and social marketing campaigns may be important for increasing support among parents who held middle-of-the-road attitudes about HPV vaccine requirements (32, 33).

Agreement with HPV vaccine school-entry requirements almost tripled when opt-out provisions were mentioned to parents, and disagreement decreased from 54% to 21%. Although vaccine opt-out provisions vary across state jurisdictions, in general, such provisions allow parents to refuse vaccination for any reasons.

Previous research showed that some parents opt out vaccination for their child, or file non-medical exemptions, because opting out is far more convenient than completing the immunization schedule for school attendance (34). Broader opt-out provisions for HPV vaccination may have the effect of creating a culture of vaccine refusal and may lead parents to seek exemptions for other vaccines (19, 35). In Virginia and Washington, D.C., parents have broad authority to opt out HPV vaccination, but procedures vary by jurisdiction. Although both jurisdictions provide parents with information about HPV infection and the benefits of vaccination,

**Figure 1.**

Agreement with school-entry requirements for HPV vaccine.

only Washington, D.C. requires parents to sign a standardized form to opt out HPV vaccination. The impact of this process on HPV vaccination is unknown. The 2014 National Immunization Survey–Teen (NIS-Teen) shows that Virginia's coverage for HPV vaccine initiation (59%) and 3-dose series completion (36%) for females aged 13–17 were below national averages (60% and 39%, respectively; ref. 5). On the other hand, Washington, D.C. had one of the highest coverage levels for HPV vaccine initiation (75%) and completion (57%) in the U.S. Research is needed to investigate the extent to which different forms of opt-out provisions may contribute to or detract from vaccination.

A growing number of states are tightening opt-out provision and non-medical exemption requirements (36). Several states, for example, require parents to submit documentation that they received information about the benefits and risks of vaccination from health care providers before opting out (37). Similar informational steps and application processes might be added to existing and future HPV vaccine school-entry requirement laws to reduce the likelihood that parents will opt-out vaccination solely for convenience. It is also important to note that vaccine advocates have expressed caution that a poorly timed push for HPV vaccine school-entry requirements or changes in opt-out provision rules might provoke a public backlash (13, 18). In light of previous failures legislating HPV vaccine requirements, such policies should be judiciously conceived and well supported by key stakeholders (13, 17).

Our data showed that parents were less likely to agree with HPV vaccine school-entry requirements if they resided in Midwest states compared with Northeast states. This finding is novel in the literature because no previous research has examined support for such requirements across U.S. regions or states. Public support for school-entry requirements is key for state legislatures to introduce and enact such proposals (17), so understanding parents' attitudes towards these requirements is important for informing state policy discussions. An analysis of HPV vaccine legislation reveals different patterns of legislative activity across U.S. regions (16). Since 2006, only half of the 12 states comprising the Midwest region introduced legislation requiring HPV vaccination for school attendance, and none of those policies was subsequently considered for enactment. In contrast, two-thirds of the 9 states in the Northeast region introduced legislation to adopt HPV vaccine school-entry requirements with Rhode Island successfully passing an administrative policy on the matter. Alternatively, three quarters of Midwestern states enacted laws to fund or educate the public or school children about HPV vaccination

versus only a third of states in the Northeast region. Taken together, these data suggested that Midwest states have responded introducing and enacting legislation aimed to increase funding and information about the vaccine rather than require HPV vaccination for school entry. Our finding that parents living in the Midwest expressed low levels of support for HPV vaccine school-entry requirements may shed some light with regard to the failure of state legislatures in introducing and passing such legislation. Although, in the absence of school-entry requirements, other laws alone are unlikely to considerably raise HPV vaccine coverage rates, laws to increase awareness of and access to HPV vaccination may serve to complement state immunization programs (38). Research on the public's opinions about a range of HPV vaccine policy strategies is needed to ensure that new legislative developments are carefully conceived and supported by state's constituents.

Support for school-entry requirements was higher among Hispanic parents compared to other racial/ethnic groups. This finding is consistent with a previous study showing that HPV vaccine requirements for school entry were highly acceptable to Hispanics (25, 39). Data from the 2014 NIS-Teen showed higher rates of HPV vaccine initiation and 3-dose completion among Hispanic adolescents aged 13–17 than their non-Hispanic white counterparts (5). Hispanics' cultural factors may explain their higher uptake of HPV vaccine and greater agreement with school-entry requirements compared with other populations (40). Robitz and colleagues (25) argued that Hispanics had a strong "respect for authority figures" and so, Hispanic parents may be more likely to agree with vaccine requirements because they are more likely to follow advice from health care professionals. Although we were unable to assess the effect of any cultural factors on the level of support for HPV vaccine school-entry requirements, previous data showed that Hispanic parents responding to survey research in Spanish were more supportive of such immunization requirements than those responding in English (25). Interestingly, other studies show a more positive effect of acculturation with regard to HPV vaccination. Gerend and colleagues (41), for example, reported that Hispanic parents who are more acculturated into U.S. society were more likely to get the HPV vaccine for their daughters. The specific mechanisms that account for the relationships between Hispanic ethnicity, acculturation, HPV vaccine uptake, and support for school-entry requirements are understudied. Nonetheless, the finding that Hispanics are consistently more supportive of HPV vaccine

^a*P* < 0.01.^b*P* < 0.05.^cRespondents from Virginia and Washington, DC. Rhode Island did not have a school-entry requirement at the time of data collection.

Figure 2.

Parental support for school-entry requirement laws with and without opt-out provisions. Black bars show the proportion of parents agreeing that HPV vaccine requirements "are a good idea," when opt-out provisions were not mentioned in the statement, and white bars show the additional proportion of parents agreeing that "these laws are okay only if parents can opt out if they want to."

school-entry requirements suggests that Hispanic communities might be important partners in advocacy and vaccine campaign mobilization efforts.

We found that parents who believed HPV vaccine was as or more important than other adolescent vaccines were more likely to support school-entry requirements. In previous surveys we conducted with family physicians and pediatricians (42, 43), many reported that they endorse HPV vaccine less strongly than Tdap or meningococcal vaccines, often discuss it last, or recommend the vaccine as an optional vaccine. These low quality recommendation practices not only discourage parents from vaccinating their children but may also add distrust and suspicion with regard to HPV vaccine policies. As physicians are an important source of vaccine information for parents (44, 45), better physician's communication practices about HPV vaccine in relation to other adolescent vaccines may influence parents' opinions about school-entry requirements. We also found that parents who had favorable perceptions of HPV vaccine effectiveness were more likely to support school-entry requirements. Our finding is consistent with previous research (25) and highlights the importance of continuing to communicate that the vaccine is a safe and effective health service to prevent cervical cancer, which kills 4,000 U.S. women each year. As HPV vaccine is recommended for boys and girls, information about parents' perceptions of vaccine effectiveness in preventing other HPV-attributable cancers may be important to increase support for school-entry requirements. Consistent with previous studies (24, 25), concerns about the involvement of drug companies in pushing HPV vaccination to make money were also associated with parents' opinions about HPV vaccine school-entry requirements. Many authors argued that drug company lobbying, while not illegal, fueled the public belief that school-entry requirements were legislated solely to benefit such companies (18, 21). Our finding suggests that efforts for maintaining public trust in public health systems are crucial both for improving HPV vaccination and for the viability of legislating school-entry requirements.

Strengths of this research include a large, national sample of parents and a good survey response rate. In addition, the current study is the first to assess support for HPV vaccine school-entry requirements after the ACIP recommended that boys be routinely vaccinated. This study had several limitations. The survey asked about hypothetical school-entry requirements, rather than actual laws, and did not describe the scope of opt-out provisions. Parents' support for school-entry requirements could differ when asked about actual legislation and may vary by type of opt-out provision (medical, religious, or philosophical exemptions). Future research should explore how support for school-entry requirements and correlates of parental support change with different types of opt-out provisions. The sample included 70% non-Hispanic Whites, which is a slightly higher proportion than the 62% of U.S. adults who identify themselves as such. Even so, our sample included meaningful numbers of non-Hispanic Black (9%) and Hispanic (14%) respondents, making this survey more racially and ethnically diverse than previous studies on this topic. Another limitation is that the survey was administered in English, so participants with limited English proficiency might have faced difficulties interpreting or responding to survey questions. Although participants needed an email account to receive an invitation to participate in the survey, the survey company facilitated the participation of respondents with lower access to technology by providing a laptop computer and free Internet access to those panel members who lacked these resources.

Although we focused on parents, we acknowledge that there are other key stakeholders contributing to policy considerations surrounding HPV vaccine school-entry requirements. Developing sound policy will require incorporating the perspectives of policymakers including whether these requirements should include nonmedical exemptions and, in such a case, the ease with which these opt-out provisions can be obtained by parents and reviewed by state officials (17). Research is needed to identify influential factors in determining how policymakers act on the issue of HPV vaccine requirements. Importantly, the perspectives of medical

associations, state health departments, and school districts are also influential to the policymaking process. A recent study showed that 47% of physicians who provide primary care, including vaccines, to adolescents support HPV vaccine school-entry requirements (46). These stakeholders have been key actors advocating about health policies in the United States (47). Because school-entry requirements are legislated on a state-by-state basis in the United States, challenges arise with regard to the capacity of states to provide school-required vaccines, monitor compliance, and enforce such policies (48). Our study provides key information about the perspectives of parents towards HPV vaccine school-entry requirements, which can inform state policy discussions about this important topic.

Conclusion

Improving HPV vaccination coverage is a national priority. While school-entry requirements have proven to be a valuable policy mechanism to raise childhood and adolescent vaccination coverage in the United States, they have also engendered controversy and debate in the case of HPV vaccination. Although school-entry requirements are viewed by some parents as an interference with parental autonomy and freedom of choice (21), through the years, other types of public health legislation (e.g., smoking restrictions, car seat belts, motorcycle helmets) have succeeded in the face of similar concerns (49). As many scholars suggest, before proposing HPV vaccine requirements states must strengthen their immunization programs and ensure that their constituents understand the benefits of HPV vaccination (18, 50). Likewise, the National Vaccine Advisory Committee recommends that states considering HPV vaccine school-entry requirements consider a range of issues including vaccine infrastructure and financing, disease burden and epidemiology, existing vaccine policies, and political and public support (35, 51). Thorough consideration of such issues will allow policymakers to address critical elements related to HPV vaccine requirements to ensure that new legislative proposals are carefully designed and supported by the public. Our study provides the first national assessment of parents' attitudes about HPV vaccine school-entry requirement; our

findings suggest that distinctive characteristics of the population may influence support for such laws. Support of school-entry requirements for HPV vaccination continues to be contingent upon the inclusion of opt-out provisions, which may negatively impact the effectiveness of these laws.

Disclosure of Potential Conflicts of Interest
